Complexity, branch points and sensitive dependence

D. Gómez-Ullate

Departmento de Física Teórica II, Universidad Complutense de Madrid

DDays - Red Dance El Escorial 22 October 2008

$$\dot{\mathbf{x}} = F(\mathbf{x}), \qquad \mathbf{x} = \mathbf{x}(t)$$

- **(1)** Las singularidades de $\mathbf{x}(t)$ en el plano *t* complejo son importantes.
- Un sistema puede ser integrable y tener dependencia sensitiva sobre condiciones iniciales.
- El estudio de la superficie de Riemann de x(t) proporciona mucha información sobre la dinámica (que resulta difícil de obtener por otros métodos)

周 ト イ ヨ ト イ ヨ

Ejemplo 1

Example 1: A system in \mathbb{C}^3

$$\begin{split} \dot{z}_1 &= -\mathrm{i}\,\omega\,z_1 + \frac{g_{12}}{z_1 - z_2} + \frac{g_{13}}{z_1 - z_3} \ ,\\ \dot{z}_2 &= -\mathrm{i}\,\omega\,z_2 + \frac{g_{21}}{z_2 - z_1} + \frac{g_{23}}{z_2 - z_3} \ ,\\ \dot{z}_3 &= -\mathrm{i}\,\omega\,z_3 + \frac{g_{31}}{z_3 - z_1} + \frac{g_{32}}{z_3 - z_2} \ . \end{split}$$

 $z_i = z_i(t), \quad z_i \in \mathbb{C}, \quad t \in \mathbb{R}$ Coupling constants $g_{ij} = g_{ji} \in \mathbb{R}$

$$\omega = 2\pi \Rightarrow T = 1$$

The complex ODEs

$$\begin{array}{rcl} \zeta_1' & = & \displaystyle \frac{g_{12}}{\zeta_1 - \zeta_2} + \frac{g_{13}}{\zeta_1 - \zeta_3} \ , \\ \zeta_2' & = & \displaystyle \frac{g_{12}}{\zeta_2 - \zeta_1} + \frac{g_{13}}{\zeta_2 - \zeta_3} \ , \\ \zeta_3' & = & \displaystyle \frac{g_{13}}{\zeta_3 - \zeta_1} + \frac{g_{23}}{\zeta_3 - \zeta_2} \ , \end{array}$$

Change of variables

$$\begin{aligned} \tau(t) &= \frac{1}{2i\omega} e^{2i\omega t} - 1 \\ z_n(t) &= e^{-i\omega t} \zeta_n(\tau) \end{aligned} \} \Rightarrow \begin{aligned} \dot{z}_1 &= -i\omega z_1 + \frac{g_{12}}{z_1 - z_2} + \frac{g_{13}}{z_1 - z_3} \\ \dot{z}_2 &= -i\omega z_2 + \frac{g_{21}}{z_2 - z_1} + \frac{g_{23}}{z_2 - z_3} \\ \dot{z}_3 &= -i\omega z_3 + \frac{g_{31}}{z_3 - z_1} + \frac{g_{32}}{z_3 - z_3} \end{aligned}$$

伺 ト イヨ ト イヨ ト

$$\begin{split} \zeta_1' &= \frac{g_{12}}{\zeta_1 - \zeta_2} + \frac{g_{13}}{\zeta_1 - \zeta_3} \;, \\ \zeta_2' &= \frac{g_{12}}{\zeta_2 - \zeta_1} + \frac{g_{13}}{\zeta_2 - \zeta_3} \;, \\ \zeta_3' &= \frac{g_{13}}{\zeta_3 - \zeta_1} + \frac{g_{23}}{\zeta_3 - \zeta_2} \;, \end{split}$$

• Translational invariance: CM motion is conserved.

$$Z(\tau) = \frac{1}{3}(\zeta_1 + \zeta_2 + \zeta_3) \Rightarrow Z' = 0 \Rightarrow Z(\tau) = Z(0)$$

Another conserved quantity

$$\zeta_1' \, \zeta_1 + \zeta_2' \, \zeta_2 + \zeta_3' \, \zeta_3 = g_{12} + g_{23} + g_{13}$$

$$\begin{split} \zeta_1' &= \frac{g_{12}}{\zeta_1 - \zeta_2} + \frac{g_{13}}{\zeta_1 - \zeta_3} \;, \\ \zeta_2' &= \frac{g_{12}}{\zeta_2 - \zeta_1} + \frac{g_{13}}{\zeta_2 - \zeta_3} \;, \\ \zeta_3' &= \frac{g_{13}}{\zeta_3 - \zeta_1} + \frac{g_{23}}{\zeta_3 - \zeta_2} \;, \end{split}$$

• Write $(\zeta_1, \zeta_2, \zeta_3)$ in terms of (Z, ρ, θ) :

$$\begin{split} \zeta_1(\tau) &= Z - \sqrt{\frac{2}{3}} \rho \cos\left(\theta + \frac{2\pi}{3}\right), \\ \zeta_2(\tau) &= Z - \sqrt{\frac{2}{3}} \rho \cos\left(\theta - \frac{2\pi}{3}\right), \\ \zeta_3(\tau) &= Z - \sqrt{\frac{2}{3}} \rho \cos\theta, \end{split}$$

$$\begin{split} \zeta_1(\tau) &= Z - \sqrt{\frac{2}{3}} \rho \cos\left(\theta + \frac{2\pi}{3}\right), \\ \zeta_2(\tau) &= Z - \sqrt{\frac{2}{3}} \rho \cos\left(\theta - \frac{2\pi}{3}\right), \\ \zeta_3(\tau) &= Z - \sqrt{\frac{2}{3}} \rho \cos\theta, \end{split}$$

Using the previous conserved quantity and trigonometric identities

$$\begin{aligned} \zeta_1^2 + \zeta_2^2 + \zeta_3^2 &= 3Z^2 + \rho^2 \Rightarrow \\ \rho^2(\tau) &= 2(g_{12} + g_{13} + g_{23})(\tau - \tau_1) \end{aligned}$$

$$\begin{split} \zeta_1' &= \frac{g_{12}}{\zeta_1 - \zeta_2} + \frac{g_{13}}{\zeta_1 - \zeta_3} \;, \\ \zeta_2' &= \frac{g_{12}}{\zeta_2 - \zeta_1} + \frac{g_{13}}{\zeta_2 - \zeta_3} \;, \\ \zeta_3' &= \frac{g_{13}}{\zeta_3 - \zeta_1} + \frac{g_{23}}{\zeta_3 - \zeta_2} \;, \end{split}$$

• The evolution of $Z(\tau)$ y $\rho(\tau)$ is integrated. Need only an equation for $\theta(\tau)$:

$$\rho^2 (\cos \theta)' (4 \cos^2 \theta - 1) = (4 g_{12} + 4 g_{13} + g_{23}) \cos \theta$$
$$-4 (g_{12} + g_{13} + g_{23}) \cos^3 \theta + \sqrt{3} (g_{23} - g_{13}) \sin \theta$$

• Call $u = \cos \theta$ and assume that $g_{23} = g_{13} = g$, $g_{12} = f$:

$$\rho^2 u' = \frac{(f+8g)u - 4(f+2g)u^2}{4u^2 - 1}$$

$$\rho^2 u' = \frac{(f+8g)u - 4(f+2g)u^3}{4u^2 - 1}$$

Since ρ^2 is linear in τ we have

$$\int \frac{d\tau}{2(2g+f)(\tau-\tau_1)} = \int du \frac{4u^2 - 1}{(f+8g)u + (4f+8g)u^3}$$

which can be integrated explicitly as

$$u^{-2\mu}\left(u^2-\frac{1}{4\mu}\right)^{\mu-1}=K(\tau-\tau_1),$$

where K is the integration constant and

$$\mu = \frac{f+2g}{f+8g}$$

One last change of variables

$$\xi = \frac{K(\tau - \tau_1)}{4\mu}$$
$$w = 4\mu u^2$$

transforms the equation

$$u^{-2\mu}\left(u^2-\frac{1}{4\mu}\right)^{\mu-1}=K(\tau-\tau_1),$$

into

$$(w-1)^{\mu-1} w^{-\mu} = \xi, \qquad \mu = \frac{f+2g}{f+8g}$$

Now work everything back to the original variables...

General solution

$$z_{1}(t) = \mathbf{Z}e^{-i\omega t} - \frac{1}{2} \left(\frac{f+8g}{6i\omega}\right)^{1/2} (1+\eta e^{-2i\omega t})^{1/2} \left[\check{w}(t)^{1/2} + (12\mu - 3\check{w}(t))^{1/2}\right]$$
$$z_{2}(t) = \mathbf{Z}e^{-i\omega t} - \frac{1}{2} \left(\frac{f+8g}{6i\omega}\right)^{1/2} (1+\eta e^{-2i\omega t})^{1/2} \left[\check{w}(t)^{1/2} - (12\mu - 3\check{w}(t))^{1/2}\right]$$
$$z_{3}(t) = \mathbf{Z}e^{-i\omega t} - \frac{1}{2} \left(\frac{f+8g}{6i\omega}\right)^{1/2} (1+\eta e^{-2i\omega t})^{1/2} \check{w}(t)^{1/2}$$

$$\check{w}(t) = w[\xi(t)] \quad \begin{cases} (w-1)^{\mu-1} w^{-\mu} = \xi \\ \xi(t) = \overline{\xi} + R e^{2i\omega t} \end{cases}$$

- The complex constants Z, η , R y $\overline{\xi}$ are fixed by the initial data (only 3 of them are independent).
- f, g, ω and μ are parameters of the problem.
- The function $\check{w}(t)$ has all the "juicy" part of the dynamics: we need to follow by continuity one of the many solutions of $(w 1)^{\mu 1} w^{-\mu} = \xi(t)$ as t evolves.

General solution

Constants Z, η , R y $\overline{\xi}$ are fixed by initial data :

$$Z = \frac{z_1(0) + z_2(0) + z_3(0)}{3},$$

$$R = \frac{3(f+8g)}{2i\omega [2z_3(0) - z_1(0) - z_2(0)]^2} \left[1 - \frac{1}{\dot{W}(0)}\right]^{\mu-1},$$

$$\eta = \frac{i\omega \left\{ [z_1(0) - z_2(0)]^2 + [z_2(0) - z_3(0)]^2 + [z_3(0) - z_1(0)]^2 \right\}}{3(f+2g)} - 1,$$

$$\dot{W}(0) = \frac{2\mu [2z_3(0) - z_1(0) - z_2(0)]^2}{[z_1(0) - z_2(0)]^2 + [z_2(0) - z_3(0)]^2 + [z_3(0) - z_1(0)]^2},$$

$$\overline{\xi} = R \eta$$
.

(note only 3 of them are independent)

イロト イヨト イヨト イヨト

Riemann surface of the solution

We must study the Riemann surface of the function $w(\xi)$ defined implicitly by

 $\Gamma = \{(\xi, w) \,|\, (w-1)^{\mu-1} \,w^{-\mu} = \xi\}$

 $\mu = p/q$ rational

- Γ is a finitely-sheeted covering of the extended ξ -plane $\mathbb{C} \cup \infty$.
- Almost all solutions are periodic, stable and isochronous.
- A set of null measure of singular orbits (collision manifolds).
- Closed formulas for the period can be written (using mostly combinatorial arguments).

μ irrational

- Γ is an infinitely-sheeted covering of the extended ξ-plane C ∪ ∞.
- Some orbits are periodic, some are aperiodic.
- Collision manifolds are dense (but null measure) on an open set of phase space.
- Sensitive dependence on initial data.

D. Gómez-Ullate Complexity, branch points and sensitive dependence

 $\mu = 37/27$

 $\mu = 56/41$

 $\mu = 227/167$

 Two nearby trajectories that pass on different sides of a BP separate (path jumps to different sheets of the RS). In the physical variables an almost collision occurs.

• c.f. analogy with polygonal billiards

A (10) A (10) A (10)

Example 2

$$\frac{d^2\zeta}{d\tau^2} = P(\zeta) = -\frac{d V(\zeta)}{d\zeta}, \qquad \tau, \zeta \in \mathbb{C}. \qquad P(\zeta), V(\zeta) \text{ are polynomials in } \zeta$$

• Circular motion:
$$\tau(t) = \tau_0 + \frac{1}{i\omega} \left(e^{i\omega t} - 1 \right)$$

• Rectilinear motion: $\tau(t) = at + b$, $a, b \in \mathbb{C}$

First integral
$$E = \frac{1}{2}(\zeta')^2 + V(\zeta)$$

Solution is formally obtained by inverting

$$\tau - \tau_0 = \int_{\zeta_0}^{\zeta} \frac{d\eta}{\sqrt{2(E - V(\eta))}}, \qquad \zeta_0 = \zeta(\tau_0)$$

• deg $V \leq 4 \Rightarrow \zeta(\tau)$ is meromorphic (single-valued)

• deg $V > 4 \Rightarrow \zeta(\tau)$ is (in general) infinitely multiple-valued

Inverting hyper-elliptic integrals

Dynamical systems on hyper-elliptic Riemann surfaces

Rectilinear motion $\tau(t) = t$

$$\ddot{z} = -(k+1)z^k, \qquad z = z(t) \in \mathbb{C}, \ t \in \mathbb{R}$$

 $k < 4 \Rightarrow$ quasi-periodic motion (c.f. irrational covering of \mathbb{T}^2)

 $k \ge 4 \Rightarrow$ sensitive dependence (c.f. polygonal billiard)

Dynamical systems on hyper-elliptic Riemann surfaces

Circular motion $\tau(t) = \tau_0 + \frac{1}{i\omega} \left(e^{i\omega t} - 1 \right)$

Surfaces of higher genus

• Consider the Riemann Surface corresponding to the curve

$$\Gamma_{2n} = \{(\eta, \mu) | \mu^2 = E - \eta^{2n} \}$$

We can view this surface as the result of identifying the opposite sides of a regular n-gon (genus is n - 1).

The center map

• The center map is a discrete 2-dim map depending on two parameters that captures the essential dynamics of the differential equation.

The center map

A region of the previous plot, magnified 10 times

The center map

A region of the previous plot, magnified 4 times more

Understanding the numerics

- For $n \leq 12$ and any radius
 - all orbits are periodic
 - period can become arbitrarily large (grows exponentially with R/I)
 - Periods of order 10^8 have been observed for $R/I \sim 20$
- For $n \ge 14$ two different behaviours:
 - For $R < R_c$, periodic behaviour (same as above).
 - 2 For $R > R_c$ aperiodic and irregular fractal behaviour

Question

Why is there a critical genus between n = 12 and n = 14 ?

A similar situation is observed in the theory of pattern formation...

The ergodic hypothesis

• The total shift of the center after N iterations of the map is given by

$$C_N = C_0 + \sum_{i=1}^N m_i V_i$$

 V_j : the possible shifts along the sides of the polygon (period vectors) m_j : net number of shifts along direction V_j .

• For aperiodic trajectories, the numerical behaviour for large N of C_N is

$$C_N \sim N^\lambda \vec{v}(N), \qquad \lambda = 1/2$$

 $\vec{v}(N)$: a random vector of order 1.

• $\lambda = 1/2$ can be interpreted as an algebraic Lyapunov exponent The motion is a random walk on an effective lattice.

The effective lattice

• Not all shifts are independent over the integers

so the dimension of the effective lattice is lower than k for a regular polygon of 2k sides.

- If n = 2k with k odd: the alternated sum of the periods is zero.
- If n = 4k with k odd, the symmetry of the polygon implies extra relations

Dimension of the effective lattice

 With this in mind, the effective dimension of the lattice as a function of the number of sides of the polygon for the first few cases is:

n	num. indep. shifts	Eff. lattice dim.		
8	4	2		
10	4	2		
12	4	2		
14	6	4		
16	8	6		

- A random walk on a 2-dim lattice comes back to the initial point with probability 1 (i.e. with probability 1 the orbit will be periodic)
- A random walk on a lattice of dimension d > 2 there is a non-zero probability of not returning to the initial point (i.e. there will be aperiodic orbits).

Summary and outlook

- The solutions of many systems of ODEs are infinitely valued functions of time.
- Information on their Riemann Surface is relevant to understanding the dynamics.
- Sensitive dependence can be understood in terms of clustering of branch points.
- Singularities on the complex time plane play a role even if time travels on the real axis.

Outlook:

- Understand how this new notion of chaos relates to existing theories
- In particular, introduce Lyapunov exponents related to this theory.
- Elaborate on Universality of this mechanism, built on the understanding of these examples.

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >
